Lucas-Interpretation from Users’ Perspective

Walther Neuper

Requirements-engineering for educational software [12] raised the question, how much efforts would be required for implementing substantial material from mechanics [13, 14] in a system based on technology from Computer Theorem Proving (TP). The question appears relevant for several kinds of “users”: for decision makers, for course designers and last not least for staff from faculties of engineering, who is interested to implement their own examples and exercises in the future.

Since TP is new in the field, there are some general informations about how to implement material in a TP-based system: First there needs to be a so-called “theory” which collects or imports all definitions used in the material and which formalises respective theorems and proofs. The system under consideration is Isac [3], a prototype based on the TP Isabelle [2]. Isabelle’s standard distribution contains most of the mathematics required, multivariate analysis [1] etc. Further material is in the Archive of Formal Proofs [1]. And what is not yet covered by these sources, can be defined as axioms preliminarily, see for instance [2]. Specification of problems is not much effort, see some prototype implementations [3]. The focus of the paper are the methods solving the problems.

The paper is organised as follows: §1 presents LI as a slight extension of usual interpreters for programming languages and introduces an example used throughout the paper [4], §2 discusses the present state and future development of Isac’s programming language. Because the latter is purely functional, without any statement for input or output, there is the question “Where are the Interactions from?” raised in §3 before a conclusion reshapes LI’s advantages for educational software.

1 A Slightly Extended Interpreter

An interpreter of a programming language works as sketched in Fig.1 on p.2: The interpreter reads a statement at a certain location in a program; the statement is interpreted such that the location moves on to another statement to be read next; the interpreter also maintains an environment, which pairs identifiers encountered in statements with respective values; a step of interpretation updates the environment according to the interpreted statement.

A Lucas-Interpreter (LI) extends the above with additional elements and actions: First a step of calculation is constructed by each step of interpretation. Guarantee of correctness for steps in calculations is the purpose of the additional elements; for logical details see [10], here follows a general explanation according to Fig.1:

A theory provides the language elements for certain logical expressions collected in a context [15]. In each step of interpretation the context provides the logical facts required to correctly deduce the next

https://intra.ist.tugraz.at/hg/isa/file/e7afa662670b/src/Tools/isac/Knowledge/Biegelinie.thy

The running example is part of another example used with another perspective in [12].
step of calculation; this action is called prove in Fig. 1. A blue square in this figure indicates, that input of a formula or tactic to the calculation is proved correct by automated provers using the current context, which is updated at each step of interpretation.

The scope of environments with respect to programs with nested sub-programs has been clarified in the discipline of compiler construction. However, the scope of contexts in the presence of theories and “locales” is not yet settled [15]. Isac uses the following scoping rules: a context is initialised by the pre-conditions at the start of interpretation, it is visible in sub-programs; the context of a sub-program remains local except predicates containing variables declared in the output of the respective sub-program.

The execution of the program’s statements is done by rewriting, as usual with functional programs (where one speaks about “evaluation” of “functions” instead of “execution” of “programs” as we do here). In the present state of Isac’s prototype there are lots of evaluators: for list-expressions in programs, for normalisation of user input (for checking correctness). for pre-conditions, etc. Compiling these evaluators is an elaborate, expensive and error-prone task. So migration of Isac’s programming language to Isabelle’s function package [5] shall free the programmer from these tasks. As soon as this integration is done, all the functions available for Isabelle/HOL are ready for LI, including those which implement computer algebra (see for instance [7, 11]).

A program is accompanied by a “guard”; guard and program together are called a “method” in Isac. The guard is not contained in Fig. 1, below an example is copied from [12] §1:

1 Guard:
11 Given: Masses $m = 2$ kg, Length $l_0 = 0.3$ m, Consts $c_1 = 1.1 \frac{kg}{s^2}, c_2 = 2.2 \frac{kg}{s^2}$, Damper $d = 0.4 \frac{Ns}{m}$
12 Where: $0 < m \land l_0 < 0$
13 Find: Matrixes $\{M(m), D(d), C(c_1, c_2)\}$, DiffEq $M \cdot \ddot{x} + D \cdot \dot{x} + C \cdot x = F$
14 Relate: $\exists x. \forall t. t > 0 \Rightarrow M \cdot \ddot{x} + D \cdot \dot{x} + C \cdot x = F$

Given in line 11 lists the concrete input items to the program, Find declares the output item(s). Where is the pre-condition, which shows, that the Guard is a conjunction of predicates restricting input (and restrictions imposed by physical contents could be added here as well). In Relate the post-condition relates input and output (in the sense of [4]); this particular post-condition can be proved by the theory of differential equations, but it is not immediately useful for an engineer, who wants the solution of an equation and not only some promise by $\exists$. 
2 The Interpreted Language

Isac’s programming language has been implemented \([9]\) before the “function package” \([5]\) has been introduced to Isabelle. But Isac’s language has been designed such, that it anticipated the function package and now the former can be explained in terms of the latter.

Functions in Isabelle/HOL must be total in order to keep the logic consistent. Isac’s programs are not total in general, their input is restricted by pre-conditions as shown in \([10]\). Thus Isac’s programs are declared as partial function in Isabelle.

A major difference between Isabelle and Isac concerns the purpose of functions: while the former is built for proving properties of functions, for evaluating them and probably generating efficient code from them, the latter is built for stepwise construction of calculations solving problems in (applied) mathematics. Construction of calculations comprises interactively specifying and solving the respective problem. Below the guard from \([10]\) above is re-used by the Specification (thus not shown again and folded in) for a Problem with a Solution as follows:

21 Problem [determine, 2-mass-oscillator, DiffEq]:

211 Specification:

212 Solution:

2121 \[ F_{c1} = c_1 x_1, \quad F_{c2} = c_2 (x_2 - x_1), \quad F_{c3} = c_1 x_2 \]

2122 forces of springs

2123 \[ F_{d1} = d \ddot{x}_1, \quad F_{d2} = d \ddot{x}_2 \]

2124 forces of dampers

2125 mass times acceleration equals sum of all forces

2126 \[ m \ddot{x}_1 = -F_{c1} + F_{c2} - F_{d1} - F_1, \quad m \ddot{x}_2 = -F_{c2} - F_{c3} - F_{d2} + F_2 \]

2127 Substitute \([F_{c1}, F_{c2}, F_{c3}, F_{d1}, F_{d2}]\)

2128 \[ m \ddot{x}_1 = -c_1 x_1 + c_2 (c_2 - x_1) - d \ddot{x}_1 - F_1, \quad m \ddot{x}_2 = -c_2 (c_2 - x_1) - c_3 x_2 - d \ddot{x}_2 + F_2 \]

2129 Rewrite Set normalise

212a \[ m \ddot{x}_1 + d \ddot{x}_1 + c_1 x_1 - c_2 (x_2 - x_1) = F_1, \quad m \ddot{x}_2 + d \ddot{x}_2 + c_2 (x_2 - x_1) + c_1 x_1 = F_2 \]

212b switch to vector representation

212c \[
\begin{pmatrix}
    m & 0 \\
    0 & m
\end{pmatrix}
\begin{pmatrix}
    \ddot{x}_1 \\
    \ddot{x}_2
\end{pmatrix}
+ \begin{pmatrix}
    d & 0 \\
    0 & d
\end{pmatrix}
\begin{pmatrix}
    \dddot{x}_1 \\
    \dddot{x}_2
\end{pmatrix}
+ \begin{pmatrix}
    c_1 + c_2 & -c_2 \\
    -c_2 & c_1 + c_2
\end{pmatrix}
\begin{pmatrix}
    x_1 \\
    x_2
\end{pmatrix}
= \begin{pmatrix}
    0 \\
    0
\end{pmatrix}
\]

22 The above Solution is considered as close to a calculation written by hand on a blackboard as possible; on the left margin there are the formulas of the calculation (indented according to the calculation’s structure), on the right margin there are the tactics and hints; the rest should be self-explanatory. The Solution is the result of Lucas-Interpretation of this program:

```
  partial_function diffq_2_mass_oscil (m, l, 0, \{c_1, c_2\}, d, springs, dampers, sums) =
  let
      springs = Take springs "forces of springs"
    parallel
      dampers = Take dampers "forces of dampers"
    parallel
      sums = Take sums "mass times acceleration equals sum of all forces"
  end_parallel
  diffeq = Take sums ""
  diffeq = Substitute \{ springs, dampers \}
  diffeq = Rewrite Set normalise
```
Lucas-Interpretation

\[ \text{diffeq} = \text{Rewrite Set vectorify “switch to vector representation”} \]

The `partial_function` `diffeq, mass_oscil` gets the arguments \((m, l_0, [c_1, c_2], d, \text{springs}, \text{dampers}, \text{sums})\) from the preceding specification phase. The first lines 2122..2126 of the calculation could have been constructed in arbitrary order; this is reflected by the lines 11..12 in the above function: the statement `parallel` models parallel execution, while the remaining statements 13..17 represent a sequence.

Above there are specific statements, called “tactics” in weak analogy to TP: `Take`, `Substitute` and `Rewrite Set` as examples for some dozen others. Tactics are handled by LI like “break points” by debuggers: interpretation halts at the tactics and passes control to the dialog component, which decides how to pass control back to LI, see the next section.

3 Where are the Interactions from?

As shown in §2 by example, a program in Isac is purely functional as is an Isabelle function, without side-effects and without input or output. However, LI creates side-effects in a specific way and cooperates with a dialogue component. The architectural design is shown in Fig.2. The `WorksheetDialog` implements the observer pattern [6] and listens to two active components: the `Worksheet` as interface to the user on the one side and to the `MathEngine` as interface to LI on the other side; the latter is active in the sense, that response may be delayed due to heavy prover activity:

![Figure 2: Isac’s dialog component](image)

Here come some details, how automated dialog generation works, by use of the running example: LI starts after successful completion of interactive specification, reads line 11 in the function on p.3 and halts at the tactic `Take`. By delivering a `CalcEvent` the `MathEngine` passes control to the `WorksheetDialog`. Now the dialogue is free to choose various kinds of interaction from the `DialogRules` according to the `UserModel`: the user can be a novice and might prefer to watch passively, or the dialog-mode is set to “exam” and forces the student to be active, ect. So, the dialog might ...

- allow the student to request the next formula (passive watching)
- suggest the kind of next step by “forces of springs”
- provide a partial next formula like \([F_{c_1} = \ldots, F_{c_2} = \ldots, F_{c_3} = \ldots]\) to be completed as shown by [12], Fig.2.
- suggest further parts of the formula (some more activity)
- enforce input of the formula (maximal activity on the student’s side): each of the lines 2122, 2124 or 2126 could be input due to the `parallel` statement. And the input formula can have
arbitrary format as long as it is algebraically equivalent, due to simplification to a normal form in the MathEngine.

- allow to review the method helping in construction of the calculation (if not in “exam” mode)
- allow to investigate Isac’s mathematics knowledge base, look at other examples and continue with the calculation eventually.
- etc.

Depending on the decision of the WorksheetDialog after some UserActions and DialogActions the respective CalcRequest is sent to the MathEngine. The latter responds with a CalcEvent, which notifies the Worksheet (by the way controlled by the WorksheetDialog) that a new CalcElement waits to be fetched from the MathEngine via a CalcIterator, which has read-access to the whole calculation under construction by LI.

The kind of interaction described above can be considered a dialog between partners on an equal base: both, the student and the system, are able to do steps of calculation more or less actively. The architecture reflects this balance, where LI is the source of power on the system side during interactive calculation.

In the present state of development the DialogRules are implemented only to an extent which allows demonstration of LI by Isac’s prototype. A general machinery [8] is ready to cope with the complexity of interaction expected in the future. Respective “dialog authoring” will be an efficient investment: interactions in doing mathematics are considered independent from various areas of mathematics; also differences in behaviour of novices versus experts are considered the same in all areas.

Relevant in the context of questions about efforts for implementation of interactive TP-based course material is: the implementation of functions is not concerned with interaction at all, a “mathematics author” can focus mathematics and nothing else.

4 Conclusion

In spite of higher complexity of TP-based systems with Lucas-Interpretation as compared with with a Computer Algebra System, the implementation of course material does not require more efforts in principle, as soon as Isac’s programming languages has migrated to Isabelle’s function package. Purely functional programs are specifically interpreted by so-called Lucas-Interpretation (LI), which generates steps of calculation and respective dialogue guidance as side-effects of steps in interpretation.

Lucas-Interpretation maintains a context, which provide the most powerful technology available with logical facts for checking correctness of user-input. Thus there is maximal freedom for input – for algorithmic sequences as well as for formula representation: equivalence modulo a theory is checked with maximal reliability. The ability to propose a next step in calculations is the novel feature contributed by Lucas-Interpretation.

No additional efforts are required when programming methods to solve engineering problems: checking steps and proposing steps is done by Lucas-Interpretation automatically and in cooperation with a dialogue module user-guidance is generated automatically.
